#### PREFACE.

In offering this book to the public, the author desires to call attention to the general scheme which has been followed.

Springs fall naturally into two classes, light and heavy: in the case of helical springs called wire and bar; in elliptical springs called sheet and plate. In the following pages the writer has considered a helical spring whose bar is less than one-sixteenth of an inch in diameter, or an elliptical spring whose plate is less than one-sixteenth of an inch in thickness, to be a light spring.

In helical springs the ratio between the diameter of the bar (or similar dimension in other than circular sections) and the mean diameter of the spring forms the basis of calculation in estimating the various properties of the spring. In elliptical springs the basis of calculation is the ratio between the thickness of the plate and the span or net length of the spring. The span or net length of a spring is the distance between centers less the width of the band.

The properties of heavy springs may be arranged easily under each size of bar or thickness of plate, inasmuch as the number of fundamental ratios for each bar is practically definite. On the other hand the numerous gauges of wire and sheet and the extremely small differences which are made in the dimensions of light springs render the number of fundamental ratios for light springs prohibitive to a table of spring properties for each gauge.

In the present tables, therefore, the writer has arranged the properties of light springs under graduated values of the fundamental ratio, so that the properties of any light spring may be quickly determined from its peculiar ratio. The properties of heavy springs are tabulated under each size bar or plate.

The table on rectangular and elliptical sections is designed for use in connection with the other tables on helical springs, the properties of springs made of such sections being easily determined by proportion. The sections considered are sections of the bar after coiling. A rectangular bar will not produce a rectangular section spring.

The mathematical tables are included to facilitate the use of formulæ.

One inch of solid height has been taken as a working basis in the case of helical springs; while for elliptical springs the basis has been taken as one plate one inch wide.

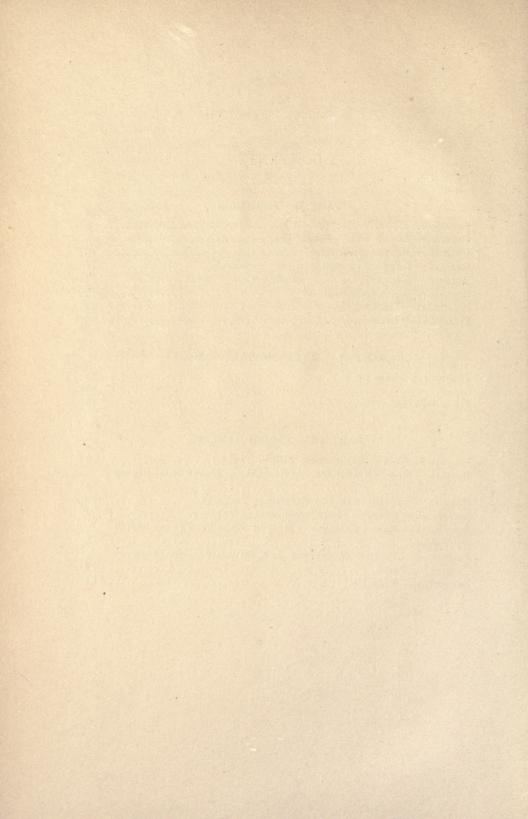

All calculations presented in this book are based on a fiber strain of 80,000 pounds per square inch. The modulus of elasticity is taken at 12,600,000 for helical springs, at 25,400,000 for elliptical springs. These figures are good practice for ordinary heavy steel springs. Calculations of springs made of material having other physical properties are simple proportions employing such properties and the tabulated values of steel springs.

Throughout the book the loads are given in pounds while all dimensions are in inches.

PART I.

FORMULÆ.

#### FORMULÆ NOTATION.

Coil: -

S =Stress solid -80,000.

G = Modulus torsional elasticity — 12,600,000.

w =Weight one cubic inch of steel

 $\pi = 3.1416.$ 

f = Deflection.

H =Free height.

h =Solid height.

 $h_1 = \text{Any height.}$ 

P =Capacity solid.

 $P_1 = \text{Load at } h_1$ .

W =Weight of spring.

L = Blunt length of bar.

D = Mean diameter of coil.

d = Diameter of round bar.

b =Width of rectangular bar.

t = Edge upon which rectangular bar is wound.

#### Elliptical: -

S =Working static stress -80,000.

E = Modulus of elasticity - 25,400,000.

P = Load.

f = Deflection.

n =Number of plates.

b = Width of plates.

h =Thickness of plates.

L= Span, equal to distance between center of bearings minus width of band, also designated C-C in tables.

r = Percentage of "blunt," or full-length leaves.

#### FORMULÆ-HELICAL, CONCENTRIC COILS.

Where  $\frac{D_1}{d_1}$  is numerically less than all other ratios of  $\frac{D}{d}$  for round bars.

Where  $H_1$  is the height of the combined coils under any load  $P_1$ . Where H, h, S, and G are the same for all coils.

For steel springs:

$$\frac{\pi S}{G}$$
 = .019946.  $\frac{G}{8}$  = 1,575,000.  $\frac{G}{3\pi}$  = 1,336,898.

Round bars:

$$h = \frac{h^{1}}{1 + \frac{\pi S}{G} \left(\frac{D_{1}}{d_{1}}\right)^{2} - \frac{P_{1}}{\frac{G}{8} \left(\frac{d_{1}^{5}}{D_{1}^{3}} + \frac{d_{2}^{5}}{D_{2}^{3}} + \frac{d_{3}^{5}}{D_{3}^{3}} + \cdots\right)}}$$

Rectangular bars:

$$h = \frac{h_1}{1 + \frac{\pi S}{G} \left( \frac{D_1^2}{t_1 \sqrt{t_1^2 + b_1^2}} \right) - \frac{P_1}{\frac{G}{3 \pi} \left[ \frac{b_1 t_1^2 (t_1^2 + b_1^2)}{D_1^3} + \cdots \right]}$$

#### HELICAL.

### RECTANGULAR AND ELLIPTICAL SECTIONS.

In designing springs it is found to be sometimes desirable to use other than the solid circular bar sections.

Rectangular and elliptical sections allow the inside, outside, and mean diameters to be retained, while the free height, deflection, or load at a given height, may be varied for a constant solid height.

The following table serves to compare the effect of the different sections possible, and may also be conveniently used in connection with the Helical Bar Table for estimating the properties of springs composed of such sections.

In a rectangular or elliptical section one-half the outside diameter of the spring less one-half the inside diameter is equivalent to "Diameter of Bar" in the Helical Bar Table. Knowing the O. D. of a rectangular or elliptical section spring and the equivalent "diameter of bar," ascertain the load and deflection under that diameter of bar and O. D. in the Helical Bar Table. Then for a rectangular or elliptical section:

For load. — Divide load given in Helical Bar Table by 31,416 and multiply by C.

For deflection.—Divide deflection given in Helical Bar Table by .019946 and multiply by K.

In the following table it is interesting to note that the product of Pf is a constant for all rectangular sections, that is, a straight line; while for elliptical sections it increases on a parabolic line to the maximum or circular value, from which it retreats on another parabolic line.

From the foregoing,

O. D. = a constant,  
I. D. = a constant,  
$$d$$
 = a constant.

while the edge upon which the bar is rolled is equal to xd, x being a variable.

	Load =	$\frac{Cd^3}{D} = P.$	Deflection per inch of Solid Height	$= K \left(\frac{D}{d}\right)^2 = f.$	Pf = MdDh

### CARRIAGE. - MEDIUM WEIGHT STEEL SPRING TABLE.

To find the load for any spring divide the constant given under P by the net length; the result will be the load at 80,000 pounds fiber strain.

To find the deflection for any spring multiply the constant given under f by the square of the net length; the result will be the deflection under the above load.

### MACHINERY AND RAILROAD. - HEAVY STEEL SPRING TABLE.

In the following tables load is for one leaf one inch wide.

For springs with a percentage of full-length leaves multiply the deflec-

tion by 
$$\frac{2}{2+r}$$
,

where

$$r = \frac{\text{No. full length leaves}}{\text{No. total of leaves}}$$
.

Fiber strain produced is 80,000 pounds per square inch.

Test load: 125 per cent of the following with deflection 125 per cent of the following.

Fiber strain, 100,000 pounds for test load.

Semi-elliptics: deflection one-half that given. Load, same.

Net length = distance C - C minus width of band.
